1Center for Vaccinology, Ghent University and Hospital, Ghent, and 2GlaxoSmithKline Biologicals, Rixensart, Belgium

**Background.** This phase I/II partially blinded, randomized, dose-ranging study assessed the safety and immunogenicity of a novel human immunodeficiency virus type 1 (HIV-1) vaccine candidate consisting of a recombinant fusion protein (F4) containing 4 HIV-1 clade B antigens (Gag p24, Pol reverse transcriptase, Nef, and Gag p17) adjuvanted with AS01 in HIV-seronegative volunteers.

**Methods.** Two doses of the recombinant F4 protein (10, 30, or 90 µg/dose), adjuvanted with AS01 or reconstituted with water for injection, were administered 1 month apart to 180 healthy volunteers aged 18–40 years. F4-specific CD4+ T cell responses were measured using intracellular cytokine staining after in vitro stimulation by overlapping peptide pools covering the 4 individual antigens.

**Results.** Reactogenicity was higher during the 7-day period after each vaccine dose in the adjuvanted than in the nonadjuvanted groups. In the adjuvanted groups, the overall immune response rate was high after the second vaccine dose, with highest responder rates seen in the 10-µg F4/AS01 group (100% to 3 HIV-1 antigens and 80% to all 4 HIV-1 antigens). High and long-lasting CD4+ T cell frequencies were observed (up to a median value of 1.2% F4-specific CD4+ T cells at day 44), with strongest responses directed against reverse transcriptase. Antigen-specific CD4+ T cells exhibited a polyfunctional phenotype, expressing at least CD40 ligand and interleukin 2, often in combination with tumor necrosis factor α and/or interferon γ. Vaccine-induced CD4+ T cell responses were broadly cross-reactive to all 4 antigens derived from HIV-1 clades A and C.

**Conclusions.** These results support further clinical investigation of this HIV-1 vaccine candidate both in a prophylactic setting (alone, in combination with an envelope-based antigen or in combination with other vaccine approaches in a heterologous prime-boost regimen) and as a potentially disease-modifying therapeutic vaccine in HIV-1–infected subjects.

Clinical trials registration. NCT00434512.

Development of a safe and effective prophylactic vaccine against human immunodeficiency virus type 1 (HIV-1) is a global health priority [1]. Three candidate HIV-1 vaccines have been tested in phase IIb or III trials. An adenovirus vector-based vaccine and bivalent recombinant gp120 protein vaccines failed to prevent HIV-1 infection [2–4], but a combination of a poxvirus vector and recombinant gp120 proteins recently demonstrated modest protection [5]. Although the most desirable goal of an HIV-1 vaccine remains the prevention of infection, a disease-modifying vaccine inducing strong T cell–mediated immune responses remains a valuable alternative.

The role of CD8+ T cell responses in controlling persistent virus infections is well established [6–9]. Virus-specific CD4+ T cells also play a central role in the immune control of many viral infections, including HIV-1 [10]. CD4+ T cells are required for the induction
and maintenance of functional CD8\(^+\) T cells [11–14], and the presence of polyfunctional and proliferation-competent HIV-1-specific CD4\(^+\) T cells in HIV-1-infected patients is associated with long-term nonprogression (LTNP) [15–17]. Loss of HIV-1-specific CD8\(^+\) T cell proliferation after acute HIV-1 infection can be restored by vaccine-induced HIV-1-specific interleukin (IL) 2-producing CD4\(^+\) T cells in vitro and in vivo [18].

A previous HIV-1 vaccine candidate comprising gp120 and a NefTat fusion protein formulated in proprietary immunostimulatory Adjuvant Systems elicited strong CD4\(^+\) T cell responses in healthy HIV-seronegative adults [19, 20] and in HIV-1-infected subjects receiving antiretroviral therapy [21]. Based on these findings and promising results with malaria [22–24] and recombinant hepatitis B virus [25] antigens, AS01—a liposome-based Adjuvant System containing 3-O-desacyl-4'-monophosphoryl lipid A (MPL) and QS21—was chosen for further investigation due to its propensity to induce a stronger CD4\(^+\) T cell response [20, 25, 26].

Because vaccine-induced CD4\(^+\) T cell responses need to cover the broadest possible spectrum of circulating HIV-1 strains, an HIV-1 vaccine should contain as many CD4\(^+\) T cell epitopes as possible from different viral proteins [27]. The viral antigens containing the highest number of conserved T cell epitopes are Gag, Pol, and Nef [28]. Given their role in HIV-1 pathogenesis and as targets for CD8\(^+\) T cell responses [29, 30], p17 and p24 encoded by gag, reverse transcriptase (RT) encoded by pol, and the regulatory protein Nef have been included as a single fusion protein (F4) in a novel vaccine formulation. This study evaluated the safety and immunogenicity of the F4 protein antigen adjuvanted with AS01 in healthy HIV-seronegative volunteers.

**MATERIALS AND METHODS**

**Study Vaccine**

The HIV-1 vaccine candidate contained 10, 30, or 90 \(\mu\)g of F4 recombinant protein per dose as an active ingredient, adjuvanted with AS01 or reconstituted with water for injection (WFI). F4 is a recombinant fusion protein expressed in *Escherichia coli* and comprising 4 HIV-1 clade B antigens: p24 (BH10), RT (HXB2), Nef (Bru-Lai), and p17 (BH10). The vaccine antigen was prepared as a lyophilized pellet containing F4 in sucrose, ethylenediaminetetraacetic acid, arginine, polysorbate 80, and sodium sulfite in phosphate buffer. AS01 is a liposome-based Adjuvant System containing 50 \(\mu\)g of MPL and 50 \(\mu\)g of QS21. The freeze-dried fraction containing the F4 antigen and the liquid fraction consisting of AS01 or WFI, both presented in a single-dose 3-mL glass vial, were reconstituted by an unblinded vaccinator, and .5 mL of the reconstituted vaccine solution was injected into the deltoid muscle of the subject’s nondominant arm.

**Study Design and Participants**

This was a phase I/II, single-center, partially blinded, parallel-group study with a dose-escalating, staggered design (NCT00434512). The study was approved by the local independent ethics committee and conducted in accordance with the Declaration of Helsinki and Good Clinical Practice guidelines, and all subjects provided written informed consent.

Participants were healthy male and female adults, aged 18–40 years; at low risk of HIV infection; seronegative for antibodies against hepatitis B core antigen, hepatitis C virus, HIV-1 and HIV-2 and negative for hepatitis B surface antigen and HIV p24 antigen in screening serum samples obtained 8 weeks before vaccination (all tests from Abbott AxSYM). Standard eligibility criteria were used for enrollment, as detailed in the ClinicalTrials.gov registry.

Subjects were randomized (5:1) to receive either AS01 (\(n = 50\)) or WFI (\(n = 10\)) for each F4 dose (10, 30, or 90 \(\mu\)g). The observers were blinded for adjuvantage but not for antigen content. Each subject received 2 vaccine doses 1 month apart. Blood samples were obtained before vaccination (day 0), 2 weeks (day 44) and 1 month (day 60) after the second vaccine dose, and at months 6 (day 180) and 12 (day 360). All laboratory assays were performed with blinding.

**Safety**

Solicited local (injection site pain, redness, swelling) and general symptoms (fever, fatigue, headache, sweating, myalgia, gastrointestinal symptoms) were recorded on diary cards for 7 days after each vaccination. Symptom severity was graded on a scale of 1–3, with grade 3 symptoms defined as redness or swelling \(>50\) mm, fever \(>39.0^\circ\)C, and any other symptom preventing normal daily activities. Unsolicited symptoms were recorded for 30 days after each vaccination. Serious adverse events were recorded throughout the study.

**T Cell Responses**

T cell responses were evaluated by intracellular cytokine staining after in vitro stimulation with p17, p24, RT, and Nef peptide pools to assess the expression of IL-2, interferon (IFN) γ, tumor necrosis factor (TNF) α, and CD40-ligand (CD40L) with an adaptation of a previously described method [31], using peripheral blood mononuclear cells (PBMCs) isolated from venous blood. In brief, thawed PBMCs were stimulated in vitro with pools of 15-mer peptides overlapping by 11 amino acids (Eurogentec) covering the sequences of clade B p17, p24, RT, or Nef matched antigens or medium only in the presence of anti-CD28 and anti-CD49d antibodies. After 2 hours at 37°C, brefeldin A was added to inhibit signal molecule secretion during an additional overnight incubation. Cells were harvested, stained for surface markers (CD4 and CD8), fixed, permeabilized, and stained with labeled antibodies to IL-2, IFN-γ, TNF-α, and CD40L (all reagents, BD Biosciences). Flow cytometric analysis...
was performed with a FACSCanto flow cytometer and FACS-Diva Version 6.1.1 (BD Biosciences) or FlowJo Version 8.8.2 (Tree Star) software.

To assess cross-reactivity of vaccine-induced CD4+ T cells with non–clade B HIV-1 antigens, PBMCs collected at days 0 and 44 were analyzed for expression of CD40L and intracellular production of IL-2, IFN-γ, and TNF-α, using peptide pools from clade A (p17 and p24 from TZA173 [Tanzania]; RT and Nef from KE MSA4070 [Kenya]) and C (ZM651) HIV-1 strains. Clade B antigens were included in the same assay as controls. This exploratory analysis was performed only on samples from subjects in the 10-μg F4/AS01 group. Amino acid alignment analysis was performed using Clustal W2 (Lasergene) and Jalview Version 2 [32] software. A subject was considered a responder if ≥0.03% antigen-specific CD4+ T cells were observed after background subtraction. This cutoff was selected based on the maximum value of all 95th percentiles for the percentage of antigen-specific CD4+ T cells expressing ≥2 markers before vaccination.

**Humoral Immune Response**

Immunoglobulin G (IgG) antibody responses to F4, p17, p24, RT, and Nef were analyzed by using standard in-house enzyme-linked immunosorbent assays. Antibody concentrations were calculated by comparing the dose-range curve from the analyzed sample with that of an in-house reference sample. All assays included negative and positive internal controls. The cutoff for seropositivity was ≥187 mEU/mL for p17, ≥119 mEU/mL for p24, ≥125 mEU/mL for RT, ≥232 mEU/mL for Nef, and ≥42 mEU/mL for F4.

**Statistical Analysis**

Analysis of safety was performed on the total vaccinated cohort. The number and percentage of subjects reporting solicited and/or unsolicited local and general symptoms were calculated with exact 95% confidence intervals (CIs).

Analysis of immunogenicity was performed on according-to-protocol cohorts at months 2 and 12. The frequency of CD4+ T cells expressing IL-2 and ≥1 other marker and the percentage of responders after in vitro stimulation to each individual antigen and to at least 1, 2, 3, and all 4 antigens were determined at each time point. The F4-specific CD4+ T cell response was estimated from the sum of the specific CD4+ T cell frequencies in response to each individual antigen. In the adjuvanted groups, F4-specific CD4+ T cell frequencies 2 weeks after the second vaccination were compared between doses by 1-way analysis of variance using the log10 frequencies, with dose (10, 30, and 90 μg) included as a fixed effect, followed by a Tukey adjustment. Statistic comparisons between groups were not performed at any other time.

Seropositivity rates and geometric mean antibody concentrations (GMCS) for F4 and each individual antigen were calculated with 95% CIs, using the exact method for binomial variables for seropositivity rates and the antilogs of the 95% CIs.

![Figure 1. CONSORT flow diagram. ATP, according to protocol.](cid.oxfordjournals.org)
of the mean log_{10}-transformed antibody concentrations for GMGs. Antibody concentrations below the assay cutoff were given an arbitrary value of half the cutoff for the GMC calculation.

RESULTS

Demographics

The mean (standard deviation) age of study participants was 22.3 (4.62) years, 63.3% were female, and 96.7% were white. No differences in baseline demographics were observed between groups. All 180 subjects received both vaccine doses, and 176 completed the study. The according-to-protocol cohort for analysis of immunogenicity comprised 152 subjects (84.4%) at month 2 and 150 (83.3%) at month 12 (Figure 1).

Safety

Reactogenicity was higher during the 7-day period after each vaccine dose in the F4/AS01 groups than in the F4/WFI groups. The incidence of local and general symptoms tended to be higher in the F4/AS01 groups after the second vaccine dose (Figure 2). Pain was the most common solicited local symptom, reported after 94.0%–98.0% of doses in the F4/AS01 groups and after 0%–40.0% of doses in the F4/WFI groups (grade 3 severity after 2.0%–12.2% of doses in the F4/AS01 groups). Fatigue was the most common solicited general symptom, reported after...

F4-specific CD4+ T cell response was estimated from the sum of the specific CD4+ T cell frequencies in response to each individual antigen. Results were expressed as the percentage of the total CD4+ T cells expressing IL-2 and ≥1 other marker (interferon γ, tumor necrosis factor α, or CD40 ligand). *P < .0001 at day 44 for 10 µg versus both 30 and 90 µg groups; statistical comparisons between groups were not performed at any other time. WFI, water for injection.

Figure 4. A, Cytokine coexpression profile of F4-specific CD4+CD40L+ T cells in the 10-µg F4/AS01 group at 2 weeks after the second dose (day 44). B, Pie charts for all time points in the 10-µg F4/AS01 group. F4-specific CD4+ T cell response was estimated from the sum of the specific CD4+ T cell frequencies in response to each individual antigen. Results were expressed as the percentage of the total CD4+CD40L+ T cells expressing 1, 2, or 3 cytokines (interleukin [IL] 2, tumor necrosis factor [TNF] α, or interferon [IFN] γ). Pie charts represent percentages as proportions. Values at day 0 were below or close to the assay cutoff (data not shown).
CD4+ T Cell Responses against Heterologous Antigens

In the 10-μg F4/AS01 group, HIV-specific CD4+ T cell responses at day 0 were below or close to the assay cutoff for all antigens across all clades (data not shown). Broadly cross-reactive CD4+ T cell responses to p17, p24, RT, and Nef peptide pools of clade A and C were seen at day 44 (Figure 5). The magnitude of the HIV-specific CD4+ T cell response against clade A and C peptides was about half that observed with corresponding clade B peptides across all antigens. Alignment analysis revealed 74%–93% identity between F4 antigens from clade B and the other clades (Table 2). All subjects mounted a response to RT and p24 from clades A and C in line with the high response rates to the corresponding homologous clade B antigens.

CD8+ T Cell Responses

Vaccine-induced CD8+ T cells were not detected by intracellular cytokine staining (data not shown).

Humoral Immune Responses

High immunoglobulin G antibody concentrations against the F4 fusion protein were seen in the AS01 groups (Figure 6). All subjects seroconverted to F4 in the adjuvanted groups, with similar IgG concentrations for all dose levels that persisted until month 12. IgG antibodies were elicited against all individual antigens (data not shown). Very low humoral immune responses were induced in the nonadjuvanted groups.

DISCUSSION

Although the most desirable goal of an HIV vaccine remains the induction of a protective immune response that prevents infection and disease, a vaccine that elicits polyfunctional CD4+ T cell responses may have disease-modifying potential. Vaccine-induced polyfunctional CD4+ T cell responses may contribute to the maintenance of a functional antiviral immune response, preventing progressive CD4+ T cell count decline, reducing or eliminating viral reservoirs, inducing long-term memory, and/or

a Data include the percentage of responders at 2 weeks after the second dose (day 44) in the 10-μg F4/AS01 group. Peripheral blood mononuclear cells collected at days 0 and 44 were analyzed by intracellular cytokine staining for the expression of CD40 ligand (CD40L) and the production of interleukin (IL) 2, interferon (IFN) γ, and tumor necrosis factor (TNF) α, using peptide pools from clades B, A (p17 and p24 from Tanzania, reverse transcriptase and Nef from Kenya), and C (ZM651) human immunodeficiency virus type 1 (HIV-1) strains. Results were expressed as the percentage of the total CD4+ T cells expressing IL-2 and >1 other marker (IFN-γ, TNF-α, or CD40L). A subject was considered a responder if the antigen-specific CD4+ response was >0.3%, the cutoff value.

conferring LTNP status on infected individuals. We recently assessed the safety and immunogenicity of a gp120/NefTat HIV-1 vaccine candidate formulated with 1 of 3 different Adjuvant Systems in healthy HIV-negative volunteers \[20\]. Strong, persistent, and broadly reactive CD4\(^+\) T cell responses were observed in all vaccine groups but were most pronounced with AS01.

This study assessed the safety and immunogenicity of a novel candidate HIV-1 vaccine consisting of the fusion protein F4 adjuvanted with AS01 in healthy HIV-seronegative volunteers. The F4/AS01 vaccine had an acceptable safety profile, consistent with clinical experience with AS01 in combination with the gp120/NefTat HIV-1 vaccine candidate \[20\], recombinant hepatitis B surface antigen \[25\], Plasmodium falciparum RTS,S \[33\], and Mycobacterium tuberculosis antigens \[34\]. The F4/AS01 vaccine elicited a high frequency of F4-specific polyfunctional CD4\(^+\) T cells that persisted until month 12. The overall rate of responders was high in all adjuvanted vaccine groups, with responses elicited against all vaccine antigens. However, the most potent CD4\(^+\) T cell responses were observed in the lowest antigen dose group (10 \(\mu\)g F4/AS01). Although all subjects who received the F4/AS01 vaccine candidate seroconverted to the F4 antigen, no significant differences in antibody responses were seen between the 3 dose groups. This might indicate important differences in the induction of T versus B cell responses by the candidate vaccine. A possible explanation for this phenomenon would be an influence of the ratio of adjuvant to antigen dose, a hypothesis merits further exploration in future studies.

Vaccine-induced CD4\(^+\) T cells expressed CD40L and produced IL-2 alone or in combination with TNF-\(\alpha\) and/or IFN-\(\gamma\). This is an important and promising observation, because antiviral CD4\(^+\) T cells producing multiple cytokines are considered functionally superior to those producing single cytokines \[35\], and their association with LTNP in HIV-1 infection is well established \[15, 16\].

HIV-1–specific CD8\(^+\) T cell responses were not detected with this vaccine. However, the vigorous CD4\(^+\) T cell responses induced may be able to provide the necessary help to CD8\(^+\) T cells induced by other vaccine strategies, such as live vectors when combined in a prime-boost regimen \[37\].

An important consideration in HIV-1 vaccine development is the diversity of the HIV-1 virus worldwide, necessitating the induction of a broadly cross-reactive immune response \[38\]. The F4/AS01 vaccine, comprising clade B antigens only, was able to elicit broadly cross-reactive CD4\(^+\) T cell responses to all 4 antigens derived from clades A and C.

Although these results are encouraging, a potential drawback of a CD4\(^+\) T cell inducing vaccine is the fact that HIV-1 preferentially infects activated CD4\(^+\) T cells, in particular HIV-1–specific CD4\(^+\) T cells \[39\]. Because any HIV-1 vaccine candidate will eventually depend on some degree of CD4\(^+\) T cell induction for an effective antiviral immune response, it may be important to evoke high levels of CD4\(^+\) T cells to tip the balance in favor of the immune system. It is reassuring that most vaccines are routinely administered to HIV-infected patients without any safety concern or clinically significant negative effect on disease progression or viral load, despite their activation or induction of CD4\(^+\) T cells \[40\]. A large phase IIb study of a trivalent...
recombinant adenovirus-based HIV-1 vaccine did not indicate any correlation between the level of activated CD4+ T cells and enhanced susceptibility to HIV-1 infection or an increased virus load in individuals who became infected during the study [41].

In conclusion, results of this study show the F4/AS01-adjuvanted HIV-1 vaccine to be immunogenic with an acceptable safety profile. Strong polyfunctional, broadly reactive and persistent CD4+ T cell responses were induced with 2 vaccine doses containing 10 µg of F4 protein adjuvanted with AS01. The properties of the immune response suggest that this vaccine candidate merits further evaluation both in a prophylactic setting (alone, in conjunction with an envelope-based antigen, or in combination with other vaccine approaches in a heterologous prime-boost regimen) and as a potentially disease-modifying therapeutic vaccine in HIV-1–infected subjects; a clinical study in such subjects has been initiated (NCT00814762).
