Artery 10

The tenth conference in a series of meetings to provide a forum for discussion on arterial structure and function

www.arterysociety.org

FINAL PROGRAMME AND

Sunday 17th - Tuesday 19th October 2010

Palazzo della Gran Guardia - VERONA, ITALY

Endorsed by

European Society of Hypertension  European Society of Cardiology

Organised in collaboration with the Working Group on Peripheral Circulation of the

Società Italiana dell’ipertensione Arteriosa
Legta Italiana contro l’ipertensione Arteriosa
P6.02 INCREASED ARTERIAL STIFFNESS IS ASSOCIATED WITH SYSTOLIC BLOOD PRESSURE VARIABILITY IN OLDER INDIVIDUALS

JC Smith, Y Yasin, LA Tomlinson, CM McEniery, IB Wilkinson

University of Cambridge, Cambridge, United Kingdom

Background: The prognostic significance of the variability in systolic blood pressure (sBP) for cardiovascular events has been highlighted recently. Although increased arterial stiffness has been proposed as a potential mechanism, the relationship between sBP variability and arterial stiffness has not been examined directly. Therefore, the aim of the current study was to determine whether increased arterial stiffness is associated with increased blood pressure variability based on 24-hour ambulatory blood pressure monitoring (ABPM) in a subset of older individuals from the Anglo-Cardiff Collaborative Trial.

Methods: Aortic stiffness was assessed by measuring the carotid-femoral pulse wave velocity (aPWV) in individuals aged over 50 years. Subjects also underwent 24-hour ABPM.

Results: Data concerning 24-hour ABPM and arterial stiffness were available in 204 individuals with an average age of 67±6 years. When individuals were grouped according to tertiles of aPWV there was a significant increase in the variability of day sBP from the lowest to highest tertile (12.52±3.72 v 14.23±3.99, P<0.001). However, this relationship was not apparent for night sBP (11.86±4.49 v 12.16±4.61, P=0.4). In stepwise linear regression analyses, aPWV was independently associated with day sBP variability after adjustment for age, gender, mean day sBP and medication. However, only mean night sBP was associated with night time sBP variability.

Conclusion: These data support the hypothesis that individuals with increased sBP variability have elevated arterial stiffness. These data require confirmation in a large population, with outcome data.

P6.03 EVOLUTION NESS AFTER KIDNEY TRANSPLANTATION IN PATIENTS WITH END-STAGE RENAL DISEASE

C Bachelet-Rousseau1, A Kearney-Schwartz2, L Frimat1, M Kessler3, A Benetos2

1Department of Nephrology, Brabois Hospital, University of Nancy, Nancy, France; 2Department of Geriatrics, Brabois Hospital, University of Nancy and INSERM U961, Nancy, France; 3Center of Clinical Investigation, Institut Lorrain du Coeur et des Vaisseaux Louis Mathieu, Nancy, France

Background: Increased arterial stiffness (AS) is a major determinant of cardiovascular complications in end-stage renal disease (ESRD) patients. Little is known about AS evolution after renal transplantation. The aim of the study was to characterize the evolution of AS after renal transplantation in a population of ESRD patients, in comparison to those patients remaining in dialysis.

Material and methods: One hundred patients were recruited from the waiting list of the Transplant Unit of the University Hospital of Nancy. Two vascular evaluations were performed at one-year interval. AS was assessed by carotid/femoral pulse wave velocity (PWV). During this interval, thirty-nine patients were transplanted and forty-nine remained on dialysis.

Results: At baseline PWV value was 10.6 ± 3.7 m/s. No difference was found between the two groups at the first and second visit. Mean arterial pressure (MAP) decreased in the transplant group (101 ± 14 vs. 95 ± 10 mmHg, p <0.01 respectively) at one-year follow up. Multivariate analysis showed that PWV changes depended on changes in MAP and baseline PWV.

Conclusion: Although no difference in the one-year PWV evolution was found, the lower MAP value in the transplanted group could result in a better long term evolution of arterial stiffness in this group, leading to a better cardiovascular prognosis after renal transplantation.

P6.04 EFFECT OF CAROTID BARORECEPTOR ACTIVATION ON AORTIC STIFFNESS

P Segers1, J Kips1, SJ Vermeersch1, D Georgakopoulos2

1Ghent University, Gent, Belgium, 2CVRx Inc., Minneapolis, MN, United States of America

Background: Previous research in acute animal models demonstrated strong effects of electrical carotid baroreceptor activation (CBA) on central hemodynamics. Data indicated arterial tone relaxation, which we could indirectly demonstrate at the level of the renal artery with a reduced impedance with CBA. The aim of this study was to assess effects of CBA on the elastic properties of the aorta.

Methods: The following data were invasively recorded in 7 anaesthetised dogs at baseline (BL) and during CBA intended to produce a moderate reduction in mean arterial pressure: (i) upper thoracic pressure (Pao; hi-fi pressure sensor) and flow (transonic flow probe) providing reflection magnitude Pb/Pf; (ii) Pao and diameter (ultrasonic crystals) providing local aortic distensibility (DC); PWV from simultaneous pressure
recordings distance 21 cm (PWV-thoracic) and 51 cm (PWV-aorta) apart.

**Results:** see Table (mean (stdev)); \(^3\)P: paired t-test.

**Discussion and Conclusion:** CBA lowered Pb/Pf and PWV, the latter effect mainly confined to the abdominal (muscular) aorta, given (i) the more substantial decrease in aortic (-1 m/s) versus thoracic (-0.4 m/s) PWV, and (ii) the absence of any change in DC measured directly at the upper thoracic aorta despite the reduction. Based on these and previous findings, we conclude that CBA modulates arterial tone in muscular arteries including the muscular parts of the aorta.

**P6.05 ARTERIAL STIFFNESS AND CARDIAC DAMAGE PROGRESSION ARE ASSOCIATED WITH ESSENTIAL HYPERTENSION PATIENTS**

**Background:** Arterial stiffness and cardiac hypertrophy are independent cardiovascular risk factors. Aim of this study was to describe the relationship between these organ damages in a large cohort of essential hypertensive (EH) treated patients.

**Methods:** We performed standard trans-thoracic echocardiography to measure anatomical (left ventricular mass indexed by body surface area [LVMi] and relative wall thickness [RWT]) and functional (ejection fraction, diastolic function [E/A] and deceleration time) cardiac parameters on 827 treated EH patients. Carotid-femoral pulse wave velocity (PWV) was used to estimate arterial stiffness. Data were analyzed by linear regressions or ANOVA and post-hoc Bonferroni test.

**Results:** Patients were 53±14 years old (Mean ± SD) and 50% were male. Their mean blood pressure values were 142.3±18.6/86.7±10.6 mmHg; cardiac structural and functional parameters were in the normal range, PWV was 10.7 m/sec. Geometry of left ventricle, as defined by LVMi and RWT (ESC guidelines), was normal in 336 (43%) patients, while in 163 (21%) we found concentric remodelling, concentric hypertrophy in 173 (22%) and eccentric hypertrophy in 109 (14%) patients. PWV was significantly different between the 4 subgroups (p = 0.001), with concentric and eccentric hypertrophy patients having significantly higher PWV values (11.5±2.7 and 11.4±3 m/sec respectively) than patients with normal heart geometry (10.2±2.6 m/sec) (p ≤ 0.001 for both).

**Conclusions:** In EH patients arterial stiffness is associated with the degree of cardiac damage. This may reflect a common pathway leading to these alterations caused by hypertension in different but tightly related organs such as heart and arteries.

**P6.06 SYSTEMIC ARTERIAL PROPERTIES DURING NORMAL PREGNANCIES IN HEALTHY WOMEN**

**Purpose:** During normal pregnancy (NP), the cardiovascular system adapts to the metabolic needs of mother and foetus with increased cardiac output (CO) and reduced vascular resistance. In NP blood pressure is not increased despite an increase of CO due to vasodilation of the resistance vessels. It is unknown whether this is also modulated by changes in the properties of the large arteries.

**Methods:** (33±1 years) with NP were investigated at gestational weeks 14-16, 22-24, 36 and 6 months postpartum (PP). Aortic root pressure and flow were obtained by calibrated right subclavian artery pulse trace, and aortic annular Doppler flow recordings. Systemic arterial properties were described by total arterial compliance(C), arterial elastance (Ea), characteristic impedance (Zo), and peripheral arterial resistance (R). Wave reflection was assessed as the ratio of the magnitude of the backward (Pb) to forward (Pf) pressure wave. Parameters were estimated by Fourier analysis of central aortic pressure and flow data and methods based on the 2-element windkessel model.

**Results:** During NP, CO increased due to increased heart rate and stroke volume, whereas, blood pressures were lower as compared to 6 months PP. R was significantly reduced accompanied by a marginally lowered Ea and Zo, whereas C was unchanged. The forward and backward pressure wave-amplitudes were significantly reduced, and reflection magnitude tended lower in mid to late pregnancy.

**Conclusions:** During NP profound alterations of systemic hemodynamics occurs, with increased cardiac output and reduced blood pressures, where the latter is related mainly to reduction in peripheral arterial resistance.
