We show that the electromagnetic superconductivity of vacuum in strong magnetic field background is consistent with the Vafa-Witten theorem because the charged vector meson condensates lock relevant internal global symmetries of QCD with the electromagnetic gauge group.

The Vafa-Witten (VW) theorem shows that vectorlike global symmetries (like isospin or baryon number) cannot be spontaneously broken in vectorlike theories (for example, in QCD) with zero theta angle [1]. According to Ref. [2], a generalization of this theorem implies that vector meson condensation cannot occur in QCD vacuum in the background of a strong magnetic field because these condensates would inevitably break certain internal global symmetries of QCD and, consequently, lead to the appearance of massless Nambu-Goldstone bosons associated with this symmetry breaking.

The presence of the charged vector condensates is crucial for the magnetic-field-induced electromagnetic superconductivity of vacuum which appears in certain hadronic models coupled to electromagnetism [3]. A sufficiently strong magnetic field, $eB \sim 1 \text{ GeV}^2$, may lead to the condensation of the charged vector mesons,

$$\rho_{\pm}(x) = \langle \bar{\psi}(x) \gamma_{\pm} \tau_{\pm} \psi(x) \rangle, \quad (1)$$

where $\psi = (u, d)^T$ is the quark spinor in Dirac, color and flavor space; $\gamma_{\pm} = (\gamma_1 \pm i\gamma_2)/2$ and $\tau_{\pm} = (\tau_1 \pm i\tau_2)/2$ are combinations of the Dirac (spinor) and Pauli (flavor) matrices, respectively. Below we demonstrate—contrary to the statement of Ref. [2]—that the presence of the non-vanishing condensates (1) in QCD in the magnetic field background is consistent with the VW theorem.

The Lagrangian of two-flavor QCD in the background of the electromagnetic field A_{μ}^{em} reads as follows:

$$\mathcal{L} = -\frac{1}{4} G_{\mu\nu}^a G^{a\mu\nu} - \bar{\psi}(i\gamma^{\mu} D_{\mu} - m)\psi, \quad (2)$$

where $G_{\mu\nu}^a$ is the strength tensor of the gluon field A_{μ}^a ,

$$D_{\mu} = \partial_{\mu} - igT^a A_{\mu}^a - iqA_{\mu}^{\text{em}}, \quad (3)$$

is the covariant derivative, T^a are generators of the $SU(3)_c$ color group and

$$q = \frac{e}{2} \left(\tau_3 + \frac{1}{3} \right) \quad (4)$$

is the electric charge matrix acting in the flavor space. For simplicity, the masses of up and down quarks are taken to be the same, $m_u = m_d = m$.

Due to the difference in electric charges of up and down quarks (4), $q_u = 2e/3$ and $q_d = -e/3$, the group of the internal continuous global symmetries of Lagrangian (2) is explicitly broken by the background electromagnetic field A_{μ}^{em} :

$$SU_V(2) \times U_B(1) \rightarrow U(1)_{I_3} \times U(1)_B, \quad (5)$$

where $U(1)_{I_3}$ is the diagonal subgroup of the isospin group $SU(2)_V$ and $U(1)_B$ is the baryon number symmetry.

The internal local symmetries of Lagrangian (2) include the electromagnetic $U(1)_{\text{em}}$ gauge symmetry

$$U(1)_{\text{em}}: \begin{cases} A_{\mu}^{\text{em}}(x) \rightarrow A_{\mu}^{\text{em}}(x) + \partial_{\mu} \omega_{\text{em}}(x) \\ \psi(x) \rightarrow \exp\{i\omega_{\text{em}}(x)q\}\psi(x) \end{cases}, \quad (6)$$

and the color $SU(3)_c$ gauge symmetry. These local symmetries are not anomalously broken so that the fermion determinant is invariant under the local $SU(3)_c \times U(1)_{\text{em}}$ gauge group. The background magnetic field itself does not break explicitly the electromagnetic gauge symmetry (6) since the magnetic field is defined by a component of the gauge invariant Abelian field strength tensor $F_{\mu\nu}^{\text{em}} = \partial_{\mu} A_{\nu}^{\text{em}} - \partial_{\nu} A_{\mu}^{\text{em}}$. Thus the Abelian symmetry (6) is the symmetry of QCD in the background of magnetic field (2) regardless if the background magnetic field is a quantized (dynamical) field or a classical (static) field.

The condensates (1) are obviously invariant under the baryonic $U(1)_B$ transformations, $\psi \rightarrow e^{i\omega_B} \psi$, while the remaining global $U(1)_{I_3}$ group, $\psi \rightarrow e^{i\omega_{I_3} \tau_3/2} \psi$, transforms the vector condensates (1) as follows:

$$U(1)_{I_3}: \rho_{\pm}(x) \rightarrow e^{\mp i\omega_{I_3}} \rho_{\pm}(x). \quad (7)$$

It was noted in Ref. [2] that a possible spontaneous breaking of the $U(1)_{I_3}$ global symmetry (7) by the vector condensates (1) contradicts the VW theorem. The spontaneous breaking of the global symmetry should give rise to appearance of a massless Nambu-Goldstone boson.

*On leave from ITEP, Moscow, Russia.

However, the corresponding massless boson does not emerge in the superconducting phase of QCD because the $U(1)_{I_3}$ global transformation (7) is, in fact, a part of the larger, electromagnetic symmetry group (6):

$$U(1)_{\text{em}}: \rho_{\pm}(x) \rightarrow e^{\mp i\omega_{\text{em}}(x)} \rho_{\pm}(x). \quad (8)$$

Equation (8) reflects the trivial fact that the vector quantities (1) are condensates of the electrically charged particles, so that they are sensitive to the electromagnetic $U(1)_{\text{em}}$ transformation (6) as well. Thus, the condensates (1) break the internal local symmetry (6) and in this case the Nambu-Goldstone boson is known to be absent [4] in agreement with the VW theorem [1]: the would-be Nambu-Goldstone boson is absorbed into the Abelian gauge field A_{μ}^{em} thus making the photon massive (as it happens in the ordinary superconductivity [4]).

Basically, the action (7) of the subgroup $U(1)_{I_3}$ of the global $SU(2)_V$ group on the condensates (1) is identical to (or, “locked with”) the action of a global subgroup of the electromagnetic $U(1)_{\text{em}}$ gauge group (8) on the same condensates.

Another argument against the breaking of the global $U(1)_{I_3}$ internal symmetry in the superconducting phase of QCD is as follows. The positive, ρ^+ , and negative, ρ^- , condensates (1)—which are, strictly speaking, independent quantities—appear simultaneously in the superconducting phase of the vacuum. These condensates have the same absolute values and opposite phases [3] stressing the fact that the superconducting vacuum is an electrically neutral state. Therefore, the vacuum state is annihilated by the conserved electric charge operator. Since the generators of the $U(1)_{\text{em}}$ and $U(1)_{I_3}$ groups are the same modulo the global $U(1)_B$ baryon symmetry (which is never broken anyway), the $U(1)_{I_3}$ charge operator annihilates the vacuum state as well. The latter fact highlights the absence of the breaking of the global internal $U(1)_{I_3}$ symmetry in the superconducting QCD phase.

As a side remark, it is worth mentioning that analytical derivations of Vafa-Witten-type theorems may contain various technical loopholes which depend on particular physical circumstances. A similar Vafa-Witten theorem

on parity violating condensates [5], for example, “cannot be regarded as an established mathematical theorem” [6]. In other words, if under certain (external) conditions the physical arguments allow for the presence of certain “VW-forbidden” condensates then the analytical proof of the VW theorem turns out to be invalid due to technical reasons related to specific features of these physical conditions. The relevant examples related to flavor and/or parity violating condensates are discussed in the context of finite temperature QCD [7], lattice regularized QCD with Wilson fermions [8], in QCD at finite isospin potential [9], etc.

Finally, we would like to stress an important difference between spontaneous breaking of external and internal continuous symmetries.¹ The spectrum of the superconducting phase of QCD should contain the massless bosonic modes associated with breaking of certain *external* (rather than *internal*) global symmetries of Lagrangian (2). These modes are related not to the fact of the very presence of the superconducting condensates (1) and not to the internal global symmetries of QCD, but rather to the spatial (“external”) inhomogeneities of the condensates (1) in the superconducting ground state of the theory. The inhomogeneous condensates possess the vortex lattice structure which breaks spontaneously translational and rotational symmetries of the vacuum [3] in a complete analogy with the mixed Abrikosov phase of the type-II superconductors [4,10]. The spontaneous breaking of these external symmetries leads to appearance of the so called “supersoft Goldstone shear modes” related to vibrations of the vortex lattice in the ground state of the theory [10].

Summarizing, we have shown that the electromagnetic superconductivity of vacuum in strong magnetic field background is consistent with the Vafa-Witten theorem.
