FLOATING UNIVERSAL QUANTIFIER AS A BASE-GENERATED HEAD IN THE VP PERIPHERY*

Dong-yi Lin
Ghent University
lindongyi@gmail.com

The universal quantifier niz in Kavalan can immediately precede its DP associate or appear in a quantifier-floating construction where it is separated from its DP associate. This paper argues that floating niz is not derived from its non-floating counterpart as a result of stranding. They differ morphosyntactically and semantically. First of all, while non-floating niz in a negative sentence exhibits scope reconstruction, floating niz in a negative sentence induces scope-freezing effect. Secondly, floating niz should be analyzed as a full-fledged verb, whereas non-floating niz is a nominal modifier. Thirdly, floating niz is not sensitive to A/A’ distinction. Fourthly, floating and non-floating niz can co-occur in a sentence. Finally, floating niz can receive interpretations that are not available to non-floating niz. The differences between floating and non-floating niz indicate that they are derivationally distinct. The fact that floating niz is morphosyntactically realized as a verb further suggests that it is base-generated in a functional head in the VP periphery.

1. Introduction

Like English all in (1) and French tous in (2), the universal quantifier niz ‘all’ in Kavalan, an Austronesian language in eastern Taiwan, can be immediately adjacent to its DP associate (3a, b) or appear in a quantifier-floating construction where it is separated from its DP associate (3c).

(1) a. [All the teachers] have finished grading finals.
   b. [The teachers] have all finished grading finals.

(2) a. [Tous les enfants] ont vu ce film.
   all the children have seen this movie
   b. [Les enfants] ont tous vu ce film.
   the children have all seen this movie

There are two major syntactic analyses of quantifier floating: Q(uantifier)-stranding and base-generation. On the Q-stranding approach proposed by Sportiche (1988), quantifier floating results from the stranding of a universal quantifier in an intermediate position where its DP associate passes (Bošković 2004; Giusti 1990; Shlonsky 1991). As depicted in (4), a universal quantifier and its DP associate originally form a QP constituent but the DP can undergo movement on its own. This results in the separation of the quantifier from its DP associate on the surface.

In contrast, advocates of the base-generation approach argue that a floating quantifier should be analyzed as a base-generated adverbial in the left periphery of VP (Baltin 1995; Doetjes 1997; Torrego 1996; Williams 1982). On this analysis, the QP headed by a floating quantifier is adjoined to VP or other functional projections in the fine-grained IP cartography.

2 The non-floating universal quantifier and its adjacent DP in (3a) and (3b) form a constituent. For example, they can be relativized together, as shown in (ib).

(i) a. m-liyam tu sudad [ya m-niz pataqsian].
   AV-read OBL book ABS AV-all student
   ‘All the students read books.’

b. [m-niz pataqsian] ya m-liyam=ay tu sudad.
   AV-all student ABS AV-read=REL OBL book

   In contrast, the universal quantifier in Malagasy and its DP associate (daholo + DP) do not form a constituent despite their linear adjacency. As illustrated by the ungrammaticality of (iib), they cannot be topicalized together.

66
The present paper aims to test the two approaches to quantifier floating against the distributional and morphosyntactic properties of Kavalan *niz*. It will be demonstrated that floating *niz* and non-floating *niz* exhibit semantic and morphosyntactic differences and are thus derivationally distinct. Quantifier floating of *niz* does not result from Q-stranding. Nevertheless, unlike English and French, where floating *all* and *tous* are an adverbial adjunct, floating *niz* is base-generated in a functional head position in the VP periphery.

Section 2 will first show that floating *niz* and non-floating *niz* observe the same restrictions regarding the type of DP/NP they can quantify over. Their similarities can be easily explained by the Q-stranding analysis of floating *niz*. However, section 3 will argue that the merits of the Q-stranding analysis are outweighed by the morphosyntactic and semantic differences between floating *niz* and non-floating *niz*. Another piece of evidence against the Q-stranding analysis concerns the word order derivation of a Q-floating construction. Section 4 concludes the study.

### 2. Floating *Niz* as a Stranded Q

On the Q-stranding analysis, floating *niz* is derived from non-floating *niz* and thus the two are expected to observe the same restriction on the type of DP/NP they can quantify over. Specifically, a DP that cannot co-occur with non-floating *niz* should not be able to bind floating *niz* either. This analysis also predicts that a DP that
cannot undergo movement should not be able to bind floating \textit{niz}. These two predictions are borne out.

2.1. Personal Proper Names and \textit{Niz}

The Q-stranding analysis predicts that floating \textit{niz} and non-floating \textit{niz} should observe the same restriction on the type of DP/NP they can quantify over. As indicated by the contrast between (6a) and (6b), personal proper names can co-occur with non-floating \textit{niz} only when they are preceded by \textit{qani-}, which denotes a group of people. Likewise, personal proper names can bind floating \textit{niz} only when they are preceded by \textit{qani-}, as illustrated in (7).

(6) a. *m-qila tu sunis [ya m-niz ti-buya, ti-imuy, ti-utay].
   \hspace{1cm} AV-scold OBL child ABS AV-all NCM-Buya NCM-Imuy NCM-Utay
   b. m-qila tu sunis [ya m-niz qani-buya, ti-imuy, ti-utay].
   \hspace{1cm} AV-scold OBLchild ABS AV-all group-Buya NCM-Imuy NCM-Utay
   ‘Buya, Imuy, and Utay all scold children.’

(7) a. *m-niz m-qila tu sunis [ti-buya, ti-imuy, ti-utay].
   \hspace{1cm} AV-all AV-scold OBL child NCM-Buya NCM-Imuy NCM-Utay
   b. m-niz m-qila tu sunis [qani-buya, ti-imuy, ti-utay].
   \hspace{1cm} AV-all AV-scold OBL child group-Buya NCM-Imuy NCM-Utay
   ‘Buya, Imuy, and Utay all scold children.’

The examples in (6) and (7) demonstrate that \textit{qani-} must be attached to personal proper names when they are quantified over by either floating \textit{niz} or non-floating \textit{niz}. The fact that they share the same restriction can be attributed to the derivational history of floating \textit{niz}, which originally forms a constituent with its DP associate and is later separated from it as a result of stranding.

2.2. DP-Movability and Quantifier Floating: Strong vs. Weak Quantifiers

The Q-stranding analysis also predicts that a DP that cannot undergo movement should not be able to bind a floating quantifier either. Before applying this test to Kavalan, I need to first discuss the distributional contrast between the strong quantifier, \textit{niz} ‘all’, and the weak quantifier, \textit{mwaza} or \textit{mazmun} ‘many, much’.\footnote{Mwaza ‘many, much’ only modifies inanimate nouns, whereas mazmun ‘many, much’ is used when animate nouns are quantified over.}

The examples in (8) and (9) illustrate the distributions of non-floating \textit{niz} and \textit{mwaza/mazmun} in different case positions. While \textit{niz} can occur in an absolutive (8a) or ergative (8b) position, it cannot occur in an oblique position (8c). In contrast, \textit{mwaza/mazmun} can only occur in an oblique position, as shown in (9).
a. qa-qila-an-na ni imuy [ya m-niz sunis].

c. *m-qila [tu m-niz sunis] ya ti-imuy.
   AV-scold OBL AV-all child ABS NCM-Imuy
   (Intended for ‘Imuy scolds all the children.’)

(9) a. *t<m>anuz tu saku [ya mazmun wasu].
   <AV>chase OBL cat ABS AV.many dog
   (Intended for ‘Many dogs chase cats.’)

   chase-PV-3ERG ERG AV.many dog ABS cat that
   (Intended for ‘Many dogs chase that cat.’)

c. t<m>anuz [tu mazmun saku] ya wasu.
   <AV>chase OBL AV.many cat ABS dog
   ‘The dog chases many cats.’

The distributions of non-floating niz and mwaza/mazmun in different case positions are summarized in Table 1. The distributional contrast between the strong and weak quantifiers can be attributed to the default definiteness interpretation of a DP in the absolutive or oblique position. A Kavalan absolutive DP must be assigned a definite interpretation (Liao 2004) and is thus incompatible with a weak quantifier such as mwaza/mazmun ‘many, much’. In contrast, a Kavalan oblique DP receives an indefinite interpretation (Liao 2004), which conflicts with the semantics of a strong quantifier such as niz ‘all’.

4 Kavalan mazmun/mwaza ‘many, much’ can appear in an absolutive or ergative position when it takes =ay.

(i) a. t<m>anuz tu saku [ya mazmun=ay wasu].

b. *mwaza m-Ramaz tu tamun ti-abas
    AV-many AV-cook OBL dish NCM-Abas

The distributional properties of niz and mwaza/mazmun seem to constitute empirical evidence for the Q-stranding analysis, which can relate their distributions to the well-known extraction restriction in Austronesian languages. On this analysis, there are two reasons why floating niz must be bound by an absolutive DP. First of all, as niz cannot co-occur with an oblique DP (8c), floating niz cannot have originated from an oblique position. Secondly, as only an absolutive DP can undergo extraction in Kavalan (Lin 2013), floating niz cannot have originated from an ergative position either. An ergative or oblique DP is unable to move to further induce stranding. The Q-stranding analysis also explains why mwaza/mazmun cannot float. As illustrated in (9), mwaza/mazmun can co-occur with an oblique DP, but not an absolutive DP. While an absolutive DP can move and is thus able to strand its modifying quantifier, as in the case of niz, an oblique DP cannot undergo movement, let alone strand mwaza/mazmun.

To summarize, the Q-stranding analysis can account for the same restriction shared by floating and non-floating niz regarding their co-occurrence with personal proper names. Moreover, it can explain why floating niz must be bound by an absolutive DP and why mwaza/mazmun cannot float. Nevertheless, as will be argued in section 3, the merits of the Q-stranding analysis are outweighed by the semantic and morphosyntactic differences between floating and non-floating niz. The fundamental differences between the two suggest that they are derivationally distinct.

3. Floating Niz as a Base-Generated Functional Head in the VP Periphery

Section 3.1 will demonstrate that floating niz is not equivalent to non-floating niz. They differ morphosyntactically and semantically and are thus derivationally distinct. Section 3.2 will further argue that the Q-stranding analysis fails to derive the correct word order of a Q-floating construction in Kavalan. The word order of floating niz, however, is not a problem for the base-generation analysis.

3.1. Semantic and Morphosyntactic Differences between Floating and Non-Floating Niz

3.1.1. Scope Interaction between Niz and Negation
According to Bošković (2004), English floating *all* induces scope-freezing effect in a negative sentence, whereas its non-floating counterpart exhibits scope reconstruction. As illustrated in (12a) and (12b), the scope of floating *all* in a negative sentence is unambiguous. When it follows the negation morpheme, negation must have a wider scope; when it precedes the negation morpheme, negation must have a narrower scope. In contrast, the scope of non-floating *all* in a negative sentence is ambiguous, as illustrated in (12c).

(12)a. The students don’t all speak Chinese. (not > all)
   b. The students all don’t speak Chinese. (all > not)
   c. All the students don’t speak Chinese. (all > not, not > all)

Likewise, non-floating *niz* in a negative sentence exhibits scope reconstruction. Either non-floating *niz* or the negation morpheme *mai* in (13a) can take wider scope over the other. Floating *niz* in a negative sentence, however, induces scope-freezing effect. (13b) and (13c) are both unambiguous. The linear order between floating *niz* and the negation morpheme *mai* determines their relative scope.

3.1.2. Morphological Differences between Floating and Non-Floating *Niz*

Floating and non-floating quantifiers in some languages, e.g., Dutch and Korean, take different morphological forms, as illustrated in (14) and (15).

(14) Dutch (Doetjes 1997: 210-211)
   a. [De kinderen] zijn allemaal gekomen.
       the children are all come
       ‘The children have all come.’
   b. *[Allemaal (de) kinderen] zijn gekomen.
   c. [Alle kinderen] zijn gekomen.
       all children are come
       ‘All of the children have come.’
The Proceedings of AFLA 22

Korean (Jaehoon Choi, personal communication)

   student-PL-NOM book-ACC all read-PST-DECL
   ‘The students read all the books.’

   student-PL-NOM all-ADJ book-ACC read-PST-DECL
   ‘The students read all the books.’

Floating and non-floating niz also differ morphologically. While non-floating niz is a nominal modifier, floating niz should be analyzed as a full-fledged verb. First of all, floating niz, but not its non-floating counterpart, can take the imperative suffix, as shown by the contrast between (16a) and (16b). Secondly, floating niz, but not non-floating niz, can take the causative prefix, as illustrated in (16c). Finally, floating niz can be affixed with the patient voice marker (16d), whereas non-floating niz cannot (16e).

Moreover, the voice markers on floating niz are verb-defining v, which can determine the argument structure of a sentence. While PV -an by itself can assign an external argument and an affected theme, AV m- cannot (Lin 2013, 2015). PV-marked niz in (17a) is thus grammatical even without a lexical verb, but this is not true of AV-marked niz in (17b).

(16a). niz-ika m-liyam [ya sudad].
   AV-IMP.PV AV-read ABS book
   ‘Read all the books!’

b. *m-liyam [ya niz-ika sudad].
   AV-read ABS all-IMP.PV book

c. pa-niz=iku [tu sunis] pa-taqsi.

   ‘I make all the children study.’

d. niz-an-na=ti ni abas q<m>an [ya byabas].
   all-PV-3ERG=PFV ERG Abas <AV>eat ABS guava
   ‘Abas ate all the guavas.’

e. *qan-an-na=ti ni abas [ya niz-an byabas].
   eat-PV-3ERG=PFV ERG Abas ABS all-PV guava

Moreover, the voice markers on floating niz are verb-defining v, which can determine the argument structure of a sentence. While PV -an by itself can assign an external argument and an affected theme, AV m- cannot (Lin 2013, 2015). PV-marked niz in (17a) is thus grammatical even without a lexical verb, but this is not true of AV-marked niz in (17b).

(17a). niz-an-na=ti ni abas [ya byabas].
   all-PV-3ERG=PFV ERG Abas ABS guava

7 In (16c), not only the universal quantifier but also the lexical verb is affixed with the causative marker pa-. The doubling of the causative marker is reminiscent of “prefix harmony” or “anticipating sequence” in Siraya (Adelaar 1997; Tsuchida 2000). Whether this Kavalan example can be subsumed under this phenomenon requires further investigation.
The Proceedings of AFLA 22

‘Abas ate/used up all the guavas.’

b. *m-niz tu byabas [ya sunis].

AV-all OBL guava ABS child

All these facts suggest that floating niz should be analyzed as a full-fledged verb that can move to v. This empirical generalization is incompatible with the Q-stranding analysis, which predicts that the stranded quantifier should be embedded inside a specifier position and cannot undergo head movement to v. Instead, as low adverbials in the VP periphery are all realized as a verb in Kavalan (Chang 2006; Lin 2014), the facts presented in (16) and (17) corroborate the analysis of floating niz as a base-generated head in the VP periphery below v.8 As illustrated in (18), low adverbials in Kavalan share the same distributional and morphosyntactic properties as a verb.

(18)a. paqanas-an-ku m-liyam ya sudad.

‘I read the book slowly.’
b. m-duna qan-an-ku ya ‘may.
AV-always eat-PV-1SG.ERG ABS rice
‘I always eat (this kind of) rice.’

3.1.3. Insensitivity to A/A’ Distinction

Sensitivity to A/A’ distinction has often been cited as evidence for the stranding analysis of quantifier floating. As indicated by the contrast between (19) and (20), a DP that undergoes A’-movement cannot strand a quantifier, unless it first undergoes short A-movement (Bobaljik 2003; Déprez 1989). A floating quantifier is only licensed in an A-chain due to its immediate adjacency to the DP-trace of its associate.

(19) (Bobaljik 2003)

a. The runners seem to themselves [t₁ to be moving very slowly].
b. The lions, might all seem (to you) [t₁ to have large teeth].
c. The lions, might all have been seen t₁ (by the tourists).

(20) (Bobaljik 2003)

a. *the professors who Taylor will have all met before the end of term
b. *These professors, Taylor will have all met before the end of term.
c. *Which professors will Taylor have all met before the end of term?

This argument, however, does not apply to Kavalan niz. In (21), the operator that floating niz quantifies over undergoes A’-movement without

---

8 cf. the high base-generation site of Malagasy daholo proposed by Koopman (2005)
incurred ungrammaticality. On the base-generation approach to floating \textit{niz}, the
grammaticality of (21) is expected, as floating \textit{niz} and its DP associate never form
a constituent and thus the movement type of the associate does not determine
whether \textit{niz} can float or not.

\begin{enumerate}
\item (21)a. \begin{vb*}
\text{byabas} [\text{RC} \text{niz-an-na}=\text{REL} \text{ni} \text{bu} \text{m-Rasa}]

\end{vb*}
\text{‘What does the dog chase all?’}
\end{enumerate}

3.1.4. Co-occurrence of Floating and Non-Floating \textit{Niz}

If floating \textit{niz} and non-floating \textit{niz} are not derivationally related, as claimed by the
base-generation approach, it is predicted that they should be able to co-occur in a
sentence. As shown in (22), this prediction is borne out.

\begin{enumerate}
\item (22) \text{niz-an-na} \text{ni} \text{abas} \text{q<m>an} [\text{ya} \text{m-niz} \text{byabas}].
\text{all-PV-3ERG} \text{ERG} \text{Abas} \text{<AV>eat} \text{ABS} \text{AV-all guava}
\text{‘Abas ate up all the guavas.’}
\end{enumerate}

The co-occurrence of floating Q and non-floating Q can also be observed in
other languages, e.g., Chinese (23), Korean (24), and Cebuano (25).

\begin{enumerate}
\item (23) Chinese
\begin{vb*}
\text{[suoyou de xuesheng]} \text{dou xihuan zhe tang ke.}
\text{all DE student all like this CLF class}
\end{vb*}
\text{‘All the students like this class.’}
\item (24) Korean (Jaehoon Choi, personal communication)
\begin{vb*}
\text{[modu-n haksayng-tul-i] modu chayk-ul ilk-ess-ta.}
\text{all-ADJ student-PL-NOM all book-ACC read-PST-DECL}
\end{vb*}
\text{‘All the students read the book.’}
\item (25) Cebuano
\begin{vb*}
\text{pulos ganahan ani nga libro [ang tanan nga mga bata].}
\text{all like this LNK book ABS all LNK PL child}
\end{vb*}
\text{‘All the children like this book.’}
\end{enumerate}
Floating Q in (22) to (25) is not a pronounced copy of the corresponding non-floating Q, as they are formally distinct from each other.

3.1.5. Interpretations of Floating Niz

Floating niz can receive interpretations that are not available to non-floating niz. Floating niz can be used as a quantifier/modifier of either entities/individuals or predicates. It can either mean ‘all’ or ‘completely; entirely’. For example, floating niz in (26a) can quantify over either the absolutive DP ya qudus-ku or the predicate tengen.

(26)a. m-niz tengen ya qudus-ku.
   AV-all black ABS clothes-1SG GEN
   ‘My clothes are completely black.’ or ‘All my clothes are black.’

b. maqen-ika m-niz q<m>an ya byabas.
   indeed-IMP PV AV-all <AV>eat ABS guava
   ‘Do eat up (all) the guavas.’ (‘consume entirely’)

Floating niz can also function as a quantifier of a set of propositions. It is similar to Chinese dou, which can quantify over a set of propositions denoted by an embedded question or a yes-no question (i.e., their possible answers), as illustrated in (27) (Cheng 1995; Cheng & Huang 1996). A corresponding Kavalan sentence is given in (28).

(27) Chinese
   a. ni guyong shei, wo dou hui bang ta.
      you hire who I all will help him
      ‘No matter who you hire, I will help him.’

   b. ta nian bu nian dou gen wo mei guanxi.
      he study NEG study all with I NEG matter
      ‘It is none of my business whether or not he studies (this).’

(28) t<m>ayta tu ti-tiana wasu zau nani, niz-an-na Raytunguz
     <AV>see OBL NCM-who dog this DM all-PV-3ERG bark
     ‘No matter who this dog sees, it barks (at him).’

3.1.6. Interim Summary

Section 3.1 has presented 5 empirical facts of niz that are opaque to the Q-stranding analysis: (1) scope-freezing effect (floating niz) vs. scope reconstruction (non-floating niz); (2) floating niz as a full-fledged verb; (3) the insensitivity of floating niz to A/A’ distinction; (4) co-occurrence of floating niz and non-floating niz; (5) floating niz as a quantifier of a set of propositions. The fundamental differences
between floating *niz* and non-floating *niz* suggest that they are derivationally distinct. Just like other low adverbials in Kavalan, floating *niz* is also morphosyntactically realized as a verb and should be analyzed as a base-generated functional head in the VP periphery.

### 3.2. Word Order of Floating *Niz*

This section will argue that the Q-stranding analysis also fails to derive the word order of a Q-floating construction in Kavalan.

Verb-initial order in Austronesian languages can be derived via either TP/VP fronting, e.g., Malagasy (Pearson 2005) and Seediq (Aldridge 2004, 2013), or verb raising, e.g., Tagalog (Aldridge 2004, 2012). On the TP/VP fronting approach, the absolutive subject moves to Spec, TopP to check the uninterpretable [D]-feature [*D*] on Top. The verb-initial word order results from the subsequent movement of the remnant TP or predicate phrase to Spec, FocP.

The verb-initial order of Tagalog, however, is derived via verb raising (Aldridge 2004, 2012). In this language, the absolutive subject undergoes covert movement to the outer specifier of vP, where it receives a definite, presuppositional interpretation. There is no TP/VP fronting. Instead, the verb-initial order is derived via verb movement to T.

On the Q-stranding analysis, [niz Erg-DP V Abs-DP], as illustrated in (29), is not a possible word order in Kavalan regardless of how Kavalan verb-initial order is derived.

\[(29) \quad \text{niz-an-na=ti} \quad \text{ni abas q<m>an} \quad [\text{ya byabas}].\]
\[\text{all-PV-3ERG=PFV} \quad \text{ERG Abas <AV>eat ABS guava}\]

‘Abas ate all the guavas.’

The derivation in (30) involves both quantifier stranding and TP fronting. The correct order of [niz Erg-DP V Abs-DP] cannot be derived. As shown in (31), on the analysis of Q-stranding, verb raising also fails to derive the word order of floating *niz*, which precedes the lexical verb in a Q-floating construction. If quantifier floating of *niz* in Kavalan results from quantifier stranding accompanied by DP movement, floating *niz* should never precede a verb, contrary to fact.

On the base-generation approach, floating *niz* is merged in a functional head position that is structurally higher than V. Its clause-initial position before V is expected no matter how Kavalan verb/predicate-initial order is derived. The derivations in (32) and (33) show that as a base-generated functional head between *v* and V, floating *niz* always precedes the lexical verb whether Kavalan verb-initial order is derived via TP fronting or verb raising.
(30) TP fronting + Q-stranding $\rightarrow$ incorrect word order

(31) verb raising + Q-stranding $\rightarrow$ incorrect word order
(32) verb raising + base-generated Q between v and V

(33) TP fronting + base-generated Q between v and V
4. Conclusion

Floating *niz* and non-floating *niz* in Kavalan differ both semantically and morphosyntactically. Floating *niz* is not derived from non-floating *niz* as a result of quantifier stranding. Non-floating *niz* is a nominal modifier, whereas floating *niz* is base-generated in a head position in the VP periphery below *v* and exhibits properties of a full-fledged verb just like other adverbial verbs in this language.
